

**COMPUTER SCIENCE 349A, SPRING 2018**  
**ASSIGNMENT #1 - 20 MARKS**

DUE TUESDAY JANUARY 22, 2019 (11:55 p.m. PST)

This is a really large class and the logistics of grading assignments are challenging. Me and the markers require your help in making this process go smoothly. Please ensure that your assignments conform to the following requirements - any violation will result in getting a zero for the particular assignment.

- All assignments should be submitted electronically through the ConneX course website and should be **SINGLE PDF FILES**. No other formats will be accepted.. Handwritten answers are ok but they will need to be scanned and merged into a single pdf file together with any code examples and associated plots.
- The assignment number, student name and student number should be clearly visible on the top of every page of your assignment submission.
- **PLEASE DO NOT COPY THE ASSIGNMENT DESCRIPTION IN YOUR SUBMISSION**
- The answers to the questions should be in the same order as in the assignment specification.
- Some of the questions of the assignments are recycled from previous years but typically with small changes in either the description or the numbers. Any submission that contains numbers from previous years in any questions will be immediately graded with zero.
- Any assignment related email questions should have a subject line of the form CSC349A Assignment X, where X is the number of the corresponding assignment.
- The total number of points for this assignment is 20.

**Question #1 - 10 marks.**

A MATLAB function M-file for Euler's method (as described in class and on pages 17-19 of the textbook) for solving the differential equation

$$\frac{dv}{dt} = g - \frac{c}{m}v$$

(this is (1.9) on page 14) is given below. As discussed in class, this numerical method is obtained by approximating  $\frac{dv}{dt}$  at time  $t_i$  by  $\frac{v(t_{i+1}) - v(t_i)}{t_{i+1} - t_i}$ , which results in the computed approximation

$$v(t_{i+1}) = v(t_i) + \left[ g - \frac{c}{m}v(t_i) \right] (t_{i+1} - t_i).$$

To create a MATLAB function M-file, either type **edit** in the Command Window or select **HOME** → **New** → **Script** or select **HOME** → **New** → **Function** (the latter gives you a template for creating a function).

Each of these options will open a new window (an Editor window) in which to type in the MATLAB statements for Euler's method. Enter the following. Statements starting with % are comments, documenting the MATLAB code.

```
function Euler(m,c,g,t0,v0,tn,n)
% print headings and initial conditions
fprintf('values of t      approximations v(t)\n')
fprintf('%8.3f',t0),fprintf('%19.4f\n',v0)
% compute step size h
h=(tn-t0)/n;
% set t,v to the initial values
t=t0;
v=v0;
% compute v(t) over n time steps using Euler's method
for i=1:n
    v=v+(g-c/m*v)*h;
    t=t+h;
    fprintf('%8.3f',t),fprintf('%19.4f\n',v)
end
```

To save your M-file, select

**EDITOR** → **Save** → **Save As...**

At the top of this window, it should say

**File name: Euler.m**

**Save as type: MATLAB files (\*.m)**

Select

**Save**

to save your file, and close the Editor window.

In order to use the above function, you must specify values for the 7 local parameters in the function Euler:

**m** is the mass of the falling object  
**c** is the drag coefficient  
**g** is the gravity constant  
**t0** is the initial time, **v0** is the initial velocity  
**tn** is the final time at which the velocity is to be computed  
**n** is the number of time steps into which  $[t_0, t_n]$  is divided

Thus, in the function **Euler**, the step size  $h = (t_n - t_0)/n$  is computed, and Euler's method is used to compute an approximation to the solution  $v(t)$  of the differential equation at the  $n$  points (values of time)

$$t_0 + h, t_0 + 2h, t_0 + 3h, t_0 + 4h, \dots, t_0 + nh = t_n.$$

For example, in order to use Euler to solve the problem given in Example 1.2 on page 17 and to save your results in a file for printing, you could enter the following (in the MATLAB Command Window):

```

diary filename
Euler ( 68.1 , 12.5 , 9.81, 0 , 0 , 12 , 6 )

```

*{the desired results should appear here}*

```

diary off

```

- (a) Create a copy of the MATLAB function Euler in your installation of MATLAB. Modify the function so that it creates and returns two matrices, one containing the times used in the calculations and one for the resulting velocities.

Note, we index matrices in MATLAB with round brackets and we start indexing at 1 NOT 0. That is, if  $t$  is a vector representing the times, then  $t(1)$  should contain time  $t_0$  and  $t(2)$  should contain time  $t_1 = t_0 + h$ , etc. The final matrices should be

$t = [t_0 \ t_1 \ \dots \ t_n]$  and  $v = [v(t_0) \ v(t_1) \ \dots \ v(t_n)]$ .

DELIVERABLES: A copy of the M-FILE in your pdf.

- (b) Use Euler to solve the differential equation using  $m = 73.5$  kg,  $c = 13.1$  kg/s and initial conditions  $v(0) = 0$  on the time interval  $[0, 16]$  using 80 time steps and for a free-falling body on Mars where the gravitational constant is  $g = 3.71$ .

DELIVERABLES: The function call to **Euler** and the resulting output.

- (c) Using the same parameters from Q1(b) solve the differential equation analytically in MATLAB. That is, create a function for the formula,

$$v(t) = \frac{gm}{c}(1 - e^{-\frac{ct}{m}}) \quad (1)$$

and run it for  $t = [t_0 : h : t_n]$ .

DELIVERABLES: The function, the call and the results.

- (d) Plot the results from Q1(b) and Q1(c) together to compare.

DELIVERABLES: The commands and resulting plot.

- (e) What is the terminal velocity of this free-falling body of mass 73.5 kg? (You may approximate this roughly with experimental results from your function or solve it analytically.)

DELIVERABLES: MATLAB output if using MATLAB or your analytic solution.

### Question #2 - 6 Marks.

Newton's law of cooling says that the temperature of a body changes at a rate proportional to the difference between its temperature and that of the surrounding medium (the ambient temperature),

$$\frac{dT}{dt} = -k(T - T_a)$$

where  $T$  is the temperature of the body ( $^{\circ}C$ ),  $t$  is time (minutes),  $k$  is the proportionality constant (per minute), and  $T_a$  is the ambient temperature ( $^{\circ}C$ ).

- (a) Modify the MATLAB function Euler in Question 1 so that it will use Euler's method to solve this differential equation. Use the function header

function Euler2(k , Ta, t0 , T0 , tn , n)

where  $T_a = T_a$ , the initial condition  $T_0 = T(t_0)$ ,  $tn$  is the final value of  $t$  in the numerical solution, and  $n$  is the number of time steps.

DELIVERABLES: A copy of the M-FILE in your pdf.

- (b) Use Euler2 to compute a numerical approximation to the above differential equation using  $k = 0.019/\text{min}$ ,  $T_a = 20^{\circ}C$  and initial condition  $T(0) = 68^{\circ}C$  on the time interval  $[0, 12]$  using a step size of 0.125 minutes.

DELIVERABLES: The function call to Euler2 and the resulting output.

- (c) Use the fact the exact analytic solution of this problem is

$$T(t) = 20 + 48e^{-0.019t}$$

to compute (either in MATLAB or using your calculator) the relative error in the computed solution at  $t = 12$ .

### Question #3 - 4 Marks

The function  $e^{-x}$  can be approximated by its McLaurin series expansion as follows (note the alternating + and -):

$$e^{-x} \approx 1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \dots \pm \frac{x^n}{n!}$$

Alternatively, note that  $e^{-x} = \frac{1}{e^x}$ . Thus,  $e^{-x}$  can also be approximated by 1 over the McLaurin series expansion of  $e^x$ . That is,

$$e^{-x} \approx \frac{1}{1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots + \frac{x^n}{n!}}$$

Approximate  $e^{-2.5}$  using both approaches above for  $n = 1, 2, 3, 4, 5, 6$  and  $7$ . Note,  $n$  is the degree of the polynomial not the number of terms. So here you use 2 terms, then 3 terms, ..., and finally 8 terms. Compare each approximation to the true value of  $e^{-2.5} = 0.082084998\dots$ , using the true relative error. What conclusions can you make about the two approaches?
